### **HiFive1** Components

Figure 1.1: HiFive1 Board

Figure 1.1 shows the HiFive1 with the parts which are described in this document.

#### **HiFive1 Schematics**

Schematics and design files for the HiFive1 are available at

http:/dev.sifive.com/hifive1

### **Required Hardware**

Using the HiFive1 Dev Kit requires the following hardware:

#### **HiFive1 Dev Kit**

SiFive's HiFive1 development board is based around the FE310-G000 chip, an SoC based around a RISC-V RV32IMAC core. It can be purchased from Crowd Supply:

http://www.crowdsupply.com/sifive/hifive1

#### **USB A to Micro-B Cable**

Any standard USB Type A Male to Micro-B Male cable can be used to interface with the HiFive1.

http://store.digilentinc.com/usb-a-to-micro-b-cable/

### **Optional Hardware**

#### **External Power Supply**

While the USB A to Micro-B cable is necessary for programming and communicating with the HiFive1, the board can run off of an external 7-12V DC supply as well, or a USB power supply or battery pack.

#### **IOREF** Jumper

Your HiFive1 comes with a single jumper for selecting the IO Reference voltage. If you need to replace it, these can be purchased from DigiKey:

http://www.digikey.com/product-detail/en/sullins-connector-solutions/SPC02SYAN/ S9001-ND/76375

#### **Compatible Shields**

Shields are devices which are designed to fit on the I/O headers on devices which match the Arduino form factor, to provide additional functionality. The shield manufacturer usually provides libraries designed to work with the Arduino IDE.

We have tested the following shields with the HiFive1 and ported their libraries.

• Adafruit's Resistive Touchscreen & LED Display:

https://www.adafruit.com/products/1651

Library: http://github.com/sifive/Adafruit\_ILI9341

• Adafruit's BLE SPI Friend:

https://www.adafruit.com/products/2633 Library: http://github.com/sifive/Adafruit\_BluefruitLE\_nRF51

Generally, shields which communicate with SPI, UART, and digital I/Os should be easy to use with the HiFive1, but their supporting library may need minor tweaks to recognize the HiFive1.

Shields with Analog input requirements will need an adapter as the FE310-G000 does not include analog components.

### 6

### **Board Setup**

### Installing the IOREF Jumper

Your HiFive1 will come with a jumper installed on J1, to select the IO Reference Level. Depending on the shields you want to drive, select 3.3V or 5.V using the jumper. You must install the jumper on one side or the other in order to drive or read any signals on the IO headers.

#### **Connecting the USB Interface**

Connect the USB Type A to Micro-B cable between the USB port of the HiFive1 and the host machine. This provides UART console access to the HiFive1 as well as a 5V power source for the board. This is also how software will be programmed and debugged on the HiFive1.

Connect the other end of the cable to your host machine. You will see the green power indication LEDs D10 and D9 light up. This means that both the main 5V supply is on, as well as the 3.3V "mostly off" supply.

### **Boot and Run**

The HiFive1 comes programmed with a simple bootloader and a demo software program which prints to the UART and cycles through the RGB LED in a rainbow pattern. You can respond on the UART to indidcate that the LEDs are changing and get a "PASS" message.

This program will be overwritten in the SPI Flash when you program new software into the board with the SDK, but the bootloader code will not be modified.

Using a terminal emulator such as GNU screen on Linux, open a console connection from the host computer to the HiFive1.

Set the following parameters:

Speed	115200
Parity	None
Data bits	8
Stop bits	1
Hardware Flow	None

For example, on Linux using GNU Screen:

```
sudo screen /dev/ttyUSB1 115200
```

Depending on your setup, you may need additional drivers or permissions to communicate over the USB port.

If you are running on Ubuntu-style Linux, the below is an example of steps you may need to follow to access your dev kit without sudo permissions:

1. With your board's debug interface connected, make sure your device shows up with the lsusb command:

```
> lsusb
...
Bus XXX Device XXX: ID 0403:6010 Future Technology Devices
International, Ltd FT2232C Dual USB-UART/FIF0 IC
```

2. Set the udev rules to allow the device to be accessed by the plugdev group:

> sudo vi /etc/udev/rules.d/99-openocd.rules

Add the following lines and save the file (if they are not already there):

```
# These are for the HiFive1 Board
SUBSYSTEM=="usb", ATTR{idVendor}=="0403",
ATTR{idProduct}=="6010", MODE="664", GROUP="plugdev"
SUBSYSTEM=="tty", ATTRS{idVendor}=="0403",
ATTRS{idProduct}=="6010", MODE="664", GROUP="plugdev"
# These are for the Olimex Debugger for use with E310 Arty Dev Kit
SUBSYSTEM=="usb", ATTR{idVendor}=="15ba",
```

10

```
ATTR{idProduct}=="002a", MODE="664", GROUP="plugdev"
SUBSYSTEM=="tty", ATTRS{idVendor}=="15ba",
ATTRS{idProduct}=="002a", MODE="664", GROUP="plugdev"
```

3. See if your board shows up as a serial device belonging to the plugdev group:

> ls /dev/ttyUSB\*
/dev/ttyUSB0 /dev/ttyUSB1

(If you have other serial devices or multiple boards attached, you may have more devices listed). For serial communication with the UART, you will always want to select the higher number of the pair, in this example /dev/ttyUSB1.

> ls -l /dev/ttyUSB1
crw-rw-r-- 1 root plugdev 188, 1 Nov 28 12:53 /dev/ttyUSB1

4. Add yourself to the plugdev group.

```
> sudo usermod -a -G plugdev <your_user_name>
```

5. Log out and log back in, then check that you're now a member of the plugdev group:

> groups ... plugdev ...

Now you should be able to access the serial (UART) and debug interface without sudo permissions.

### **Terminal Log**

If you have your serial setup correctly, this is what you will see on your terminal:

### **Software Development Flow**

The HiFive1's boot code contains a jump to the external SPI Flash on the board, at address 0x20400000. You can change the program which the dev kit runs by using the debug/programming interface to flash a new compiled program into the SPI Flash.

SiFive supports two methods of obtaining the software development toolchain: compiling the Freedom E SDK from source, and installing precompiled tools using the Arduino IDE. The two techniques will install the same set of tools, but the install paths and associated software libraries are different.

#### **Supported Platforms**

This document assumes that you are running on a Linux system, either natively or on a Linux Virtual Machine. Future versions of this document will include details on how to install on other platforms.

#### Software Development with the Freedom E SDK

#### **Compiling the Freedom E SDK Toolchain**

The Freedom E Software Development Kit provides everything required to compile, customize, and debug C and/or RISC-V assembly programs: GCC 6.1.0 cross-compilation toolchain, RISC-V enabled GDB and OpenOCD, etc.

To clone the Freedom E SDK git repository:

```
git clone --recursive https://github.com/sifive/freedom-e-sdk.git
```

Install all the necessary packages described in the repository's README.md file.

To build the software toolchain:

```
cd freedom-e-sdk make tools
```

To keep your software toolchain up to date with the upstream repository:

```
cd freedom-e-sdk
git pull origin master
git submodule update --init --recursive
make tools
```

### **Compiling Software Programs**

To build a C program that will be loaded by the debugger/programmer into the SPI Flash, use the Freedom E SDK to compile. An example is provided in the software/demo\_gpio directory. To build the program:

```
cd freedom-e-sdk
make software PROGRAM=demo_gpio BOARD=freedom-e300-hifive1
```

To compile the Dhrystone benchmark instead:

```
cd freedom-e-sdk
make software PROGRAM=dhrystone BOARD=freedom-e300-hifive1
```

### **Uploading Software Programs**

To upload the program to the SPI flash, connect the board's debug interface as described in Chapter 4. Then execute:

```
cd freedom-e-sdk
make upload PROGRAM=<your desired program> BOARD=freedom-e300-hifive1
```

#### **Debugging Running Programs**

To debug your program with GDB, connect your board and launch the debugger:

```
cd freedom-e-sdk
make run_debug PROGRAM=<your desired program> BOARD=freedom-e300-hifive1
```

This will automatically launch OpenOCD and GDB, connect to the board, and halt the currently running program. You can step through the running program with stepi, or load the new program using load. The usual suite of GDB commands are available to set breakpoints, examine and modify memory, continue execution, etc.

#### Software Development Using the Arduino IDE

SiFive also supports software development for the HiFive1 with the Arduino IDE. When using this method, the Freedom E SDK is automatically installed, so you do not need to install it seperately. Follow these steps:

#### Installing the HiFive1 Board Package

- Download and install the Arduino IDE, following the instructions at https://www.arduino.cc/en/Guide/HomePage
- 2. Launch the Arduino IDE
- 3. Navigate to File  $\rightarrow$  Preferences and add the SiFive additional Board Manager URL as shown in Figure 6.1:

http://static.dev.sifive.com/bsp/arduino/package\_sifive\_index.json

4. Add the SiFive development kit boards using the Board Manager:

 $\texttt{Tools} \ \rightarrow \ \texttt{Board} \ \rightarrow \ \texttt{Board} \ \texttt{Manager}.$ 

Search for "SiFive" and click Install to download and install the package. Restart your Arduino IDE, then find the HiFive1 under Tools  $\rightarrow$  Board, as shown in Figure 6.2.

- 5. Select SiFive OpenOCD as the Programmer from the Tools menu.
- 6. To compile and upload a simple example program, select

 $\texttt{File} \ \rightarrow \ \texttt{Examples} \ \rightarrow \ \texttt{Basics} \ \rightarrow \ \texttt{Blink}$ 

Click the "upload" button in the Arduino IDE, your program will compile and upload to your Dev Kit, and the green LED will blink.

### **Open Source Board Support Package Code**

The code installed with the Board package is open-source, and available to view or download at:

http://github.com/sifive/cinco

### **HiFive1 Additional Notes**

This chapter gives some additional information about how your FE310-G000 chip is configured on the HiFive1 board.

To understand the FE310-G000 internals, please refer to

https://dev.sifive.com/documentation/freedom-e310-g000-manual/

### Freedom E310 Pinout

The Freedom E310 design on the HiFive1 has 32 SW-accessible GPIO registers. Not all of these are available on the 48-pin package and are therefore not connected to the GPIO Headers on the board. Table 7.1 gives the mapping between the software GPIO offset and labeled pin on the board.

HiFive1 Pin Number	GPIO Offset	IOF0	IOF1	LED
0	16	UART0:RX		
1	17	UART0:TX		
2	18			
3	19		PWM1_1	GREEN
4	20		PWM1_0	
5	21		PWM1_2	BLUE
6	22		PWM1_3	RED
7	23			
8	0		PWM0_0	
9	1		PWM0_1	
10	2	SPI1:SS0	PWM0_2	
11	3	PI1:SD0/MOSI	PWM0_3	
12	4	SPI1:SD1/MISO		
13	5	SPI1:SCK		
14		Not Connected		
15	9	SPI1:SS2		
16	10	SPI1:SS3	PWM2_0	
17	11		PWM2_1	
18	12		PWM2_2	
19	13		PWM2_3	

Table 7.1: HiFive1 GPIO Offset to Board Pin Number

Figure 8 gives a graphical depition of the HiFive1's pin functions.

#### **OTP Contents**

The FE310-G000 on the HiFive1 board contains a one-time programmable memory (OTP). This OTP is shipped with code that enables your HiFive1 to boot out of reset (vs. loading a program with the programmer and running it). The OTP also contains trim values for the high-frequency oscillator on your FE310-G000 and a unique identifier.

The OTP contents are critical for the proper functioning of your FE310-G000 and HiFive1 board. You are strongly discouraged from modifying the OTP contents. OTP contents can NOT be restored if modified.

OTP Offset	Value	Eigld Description
		Field Description
0x0000	7f50106f	Reset Vector from 0x1000. Exe-
	(j 0x1FF4)	cutes a relative jump to the last
		fence block in the OTP.
0x0004	00000000	Included Config String from
		0x1004. This is left unburned as
		the Config String specification is
		not yet finalized.
0x1FE4	Varies	Board Identifier
0x1FE8	0000000	LFROSC Trim Setting, left un-
		burned on HiFive1
0x1FEC	Varies	HFROSC Trim Setting for 72MHz
0x1FF0	0x0000001	Indicates the other fields were suc-
		cessfully programmed
0x1FF4	0x000000F	This functions as a NOP which al-
	(fence)	lows later modification of the pro-
		gram the OTP executes. This word
		could be modified to a short rel-
		ative jump elsewhere in the OTP.
		The target instruction block should
		also start with a fence instruction
		to allow later modifications to be
		chained in this way.
0x1FF8	200002b7	Load to with 0x20000000
	(lui tO,	
	0x20000)	
0x1FFC	00028057	Jump to start of SPI Flash
	(jr t0)	
	,	

Table 7.2: HiFive1 Default OTP Contents

#### **HiFive1 Boot Sequence**

The HiFive1 Board is shipped with a modifiable boot loader at the begnning of SPI Flash (0x2000000). At the end of this program's execution the core jumps to the main user portion of code at 0x20400000. This program is designed to allow quick boot, but also a "safe" reboot option if a "bad" program is flashed into the HiFive1's SPI Flash. A "bad" program is one which makes it impossible for the programmer to communicate with the HiFive1. For example, a program which disables FE310's active clock, or which puts the FE310 to sleep with no way of waking it up. Bad programs can always be restarted using the RESET button, and using the "safe" bootloader can be halted before they perform any unsafe behavior.

To activate "normal" boot mode, press the RESET button on the HiFive1. After approximately 1s, the green LED will flash for 1/2 second, then the user program will execute.

To activate "safe" boot mode, press the RESET button. When the green LED flashes, immediately press the RESET button again. After 1 second, the red LED will blink. The user program will not execute, and the programmer can connect. To exit "safe" boot mode, press the RESET button a final time.

### **For More Information**

Additional information, the latest version of this guide, and supporting files can be found at http://dev.sifive.com/hifive1.
